The growing impact of satellite megaconstellation launch and re-entry emissions on radiative forcing and stratospheric ozone depletion

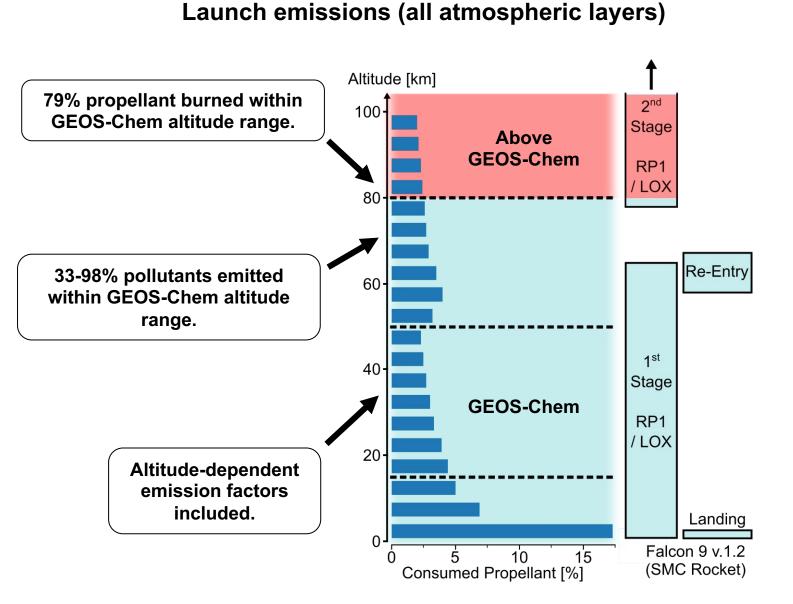

Launches (all atmospheric layers)

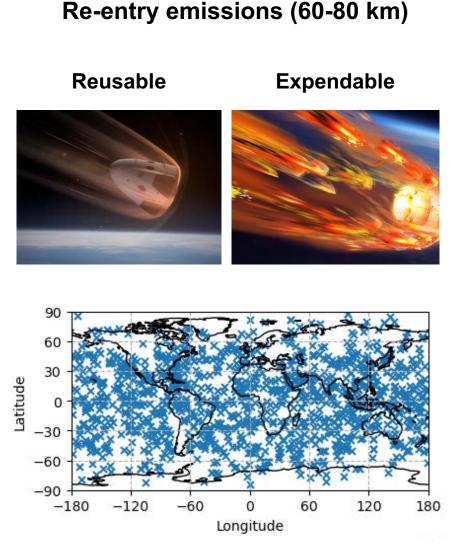

Developing 3D emission inventories of rocket launches and re-entries

UCL

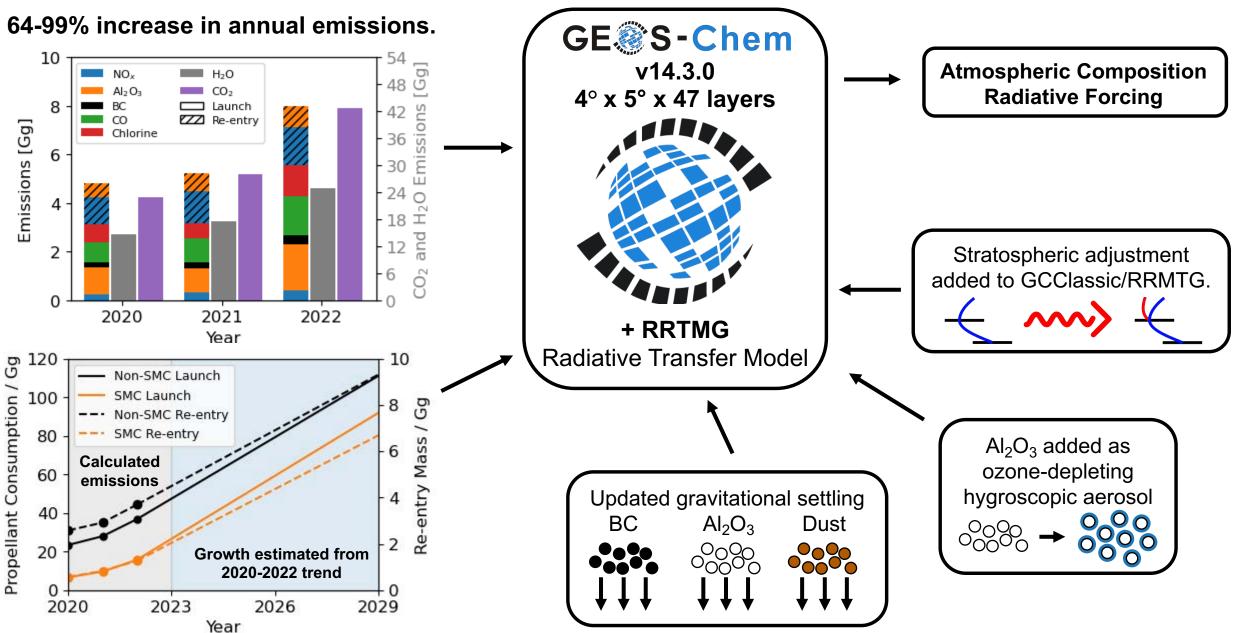

Annual propellant consumption has increased from 38-67 Gg.

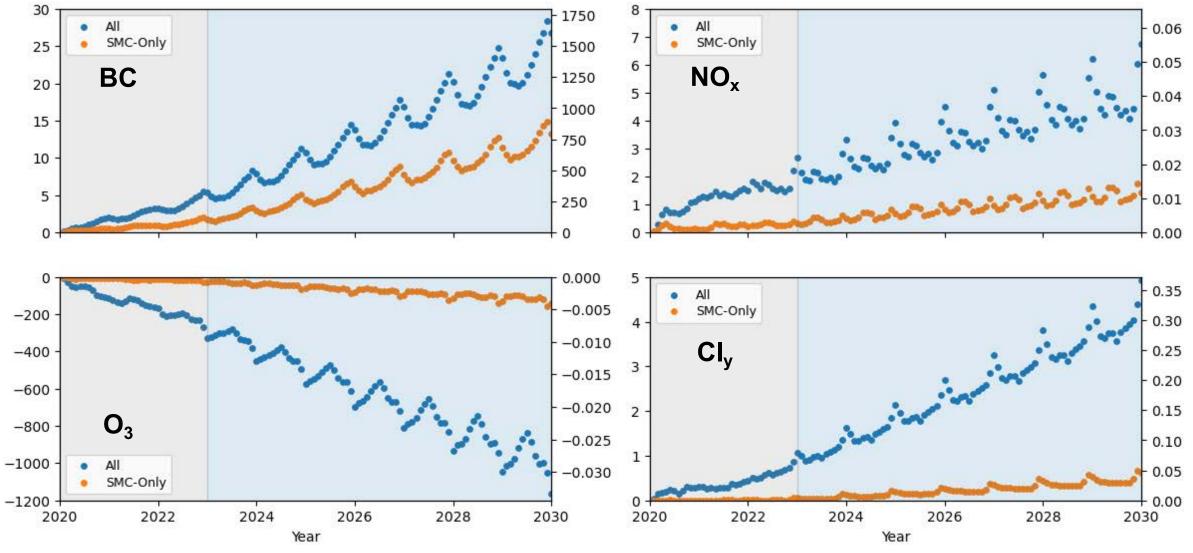

Annual re-entry mass (5 Gg) is now ~40% of natural influx (26% SMC). 2 kt unablated mass returns to Earth.

Implementing annual emissions into GEOS-Chem

Impact of space industry emissions on stratospheric concentrations

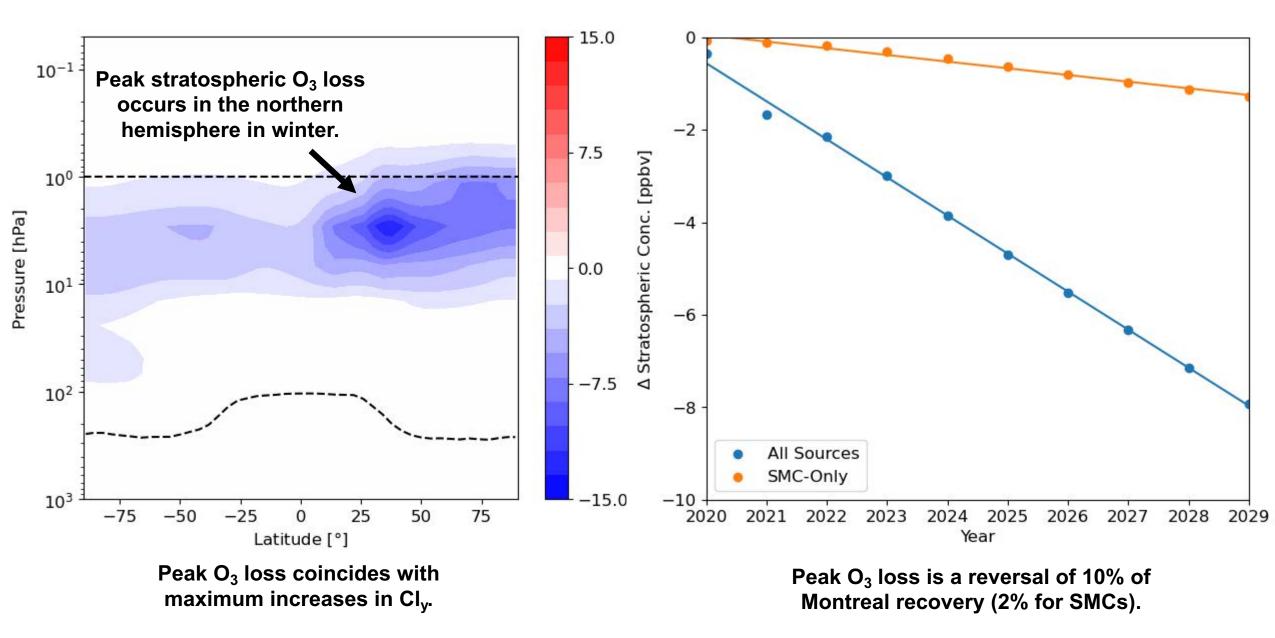

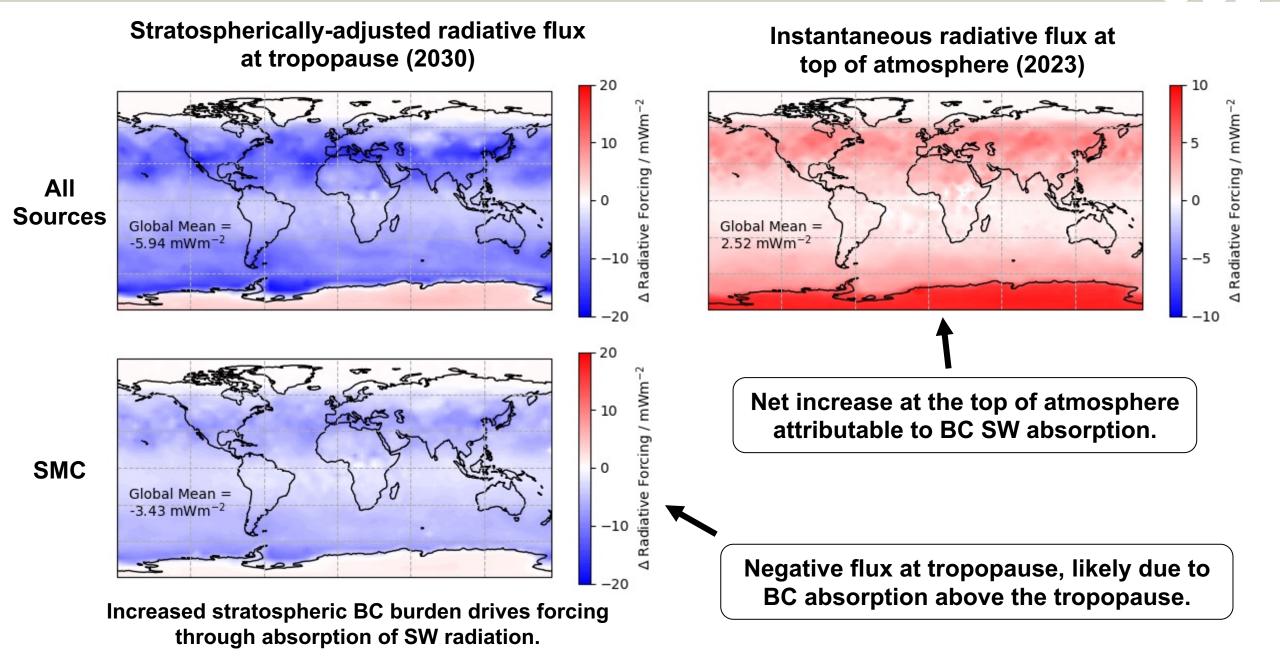

Global Stratospheric Mean Concentrations

Minimal O₃ loss from SMCs but significant BC emissions.

A Stratospheric Conc. [pptv]

Minimal increases in ozone depleting emissions from SMCs.

Summary

- Developed SMC and non-SMC emission inventories for 2020-2022.
- Preliminary results demonstrate immediate environmental impacts.
 - A decade of increasing rocket launch and re-entry emissions reverse 10% of Montreal Protocol gains.
 - SMCs cause negligible O_3 depletion but lead to large increases in stratospheric BC.
 - Increasing rocket launch and re-entry emissions cause decrease in stratospherically-adjusted tropopause flux and increase in instantaneous TOA flux.
 - SMCs affect climate through significant emissions of BC above the tropopause.
