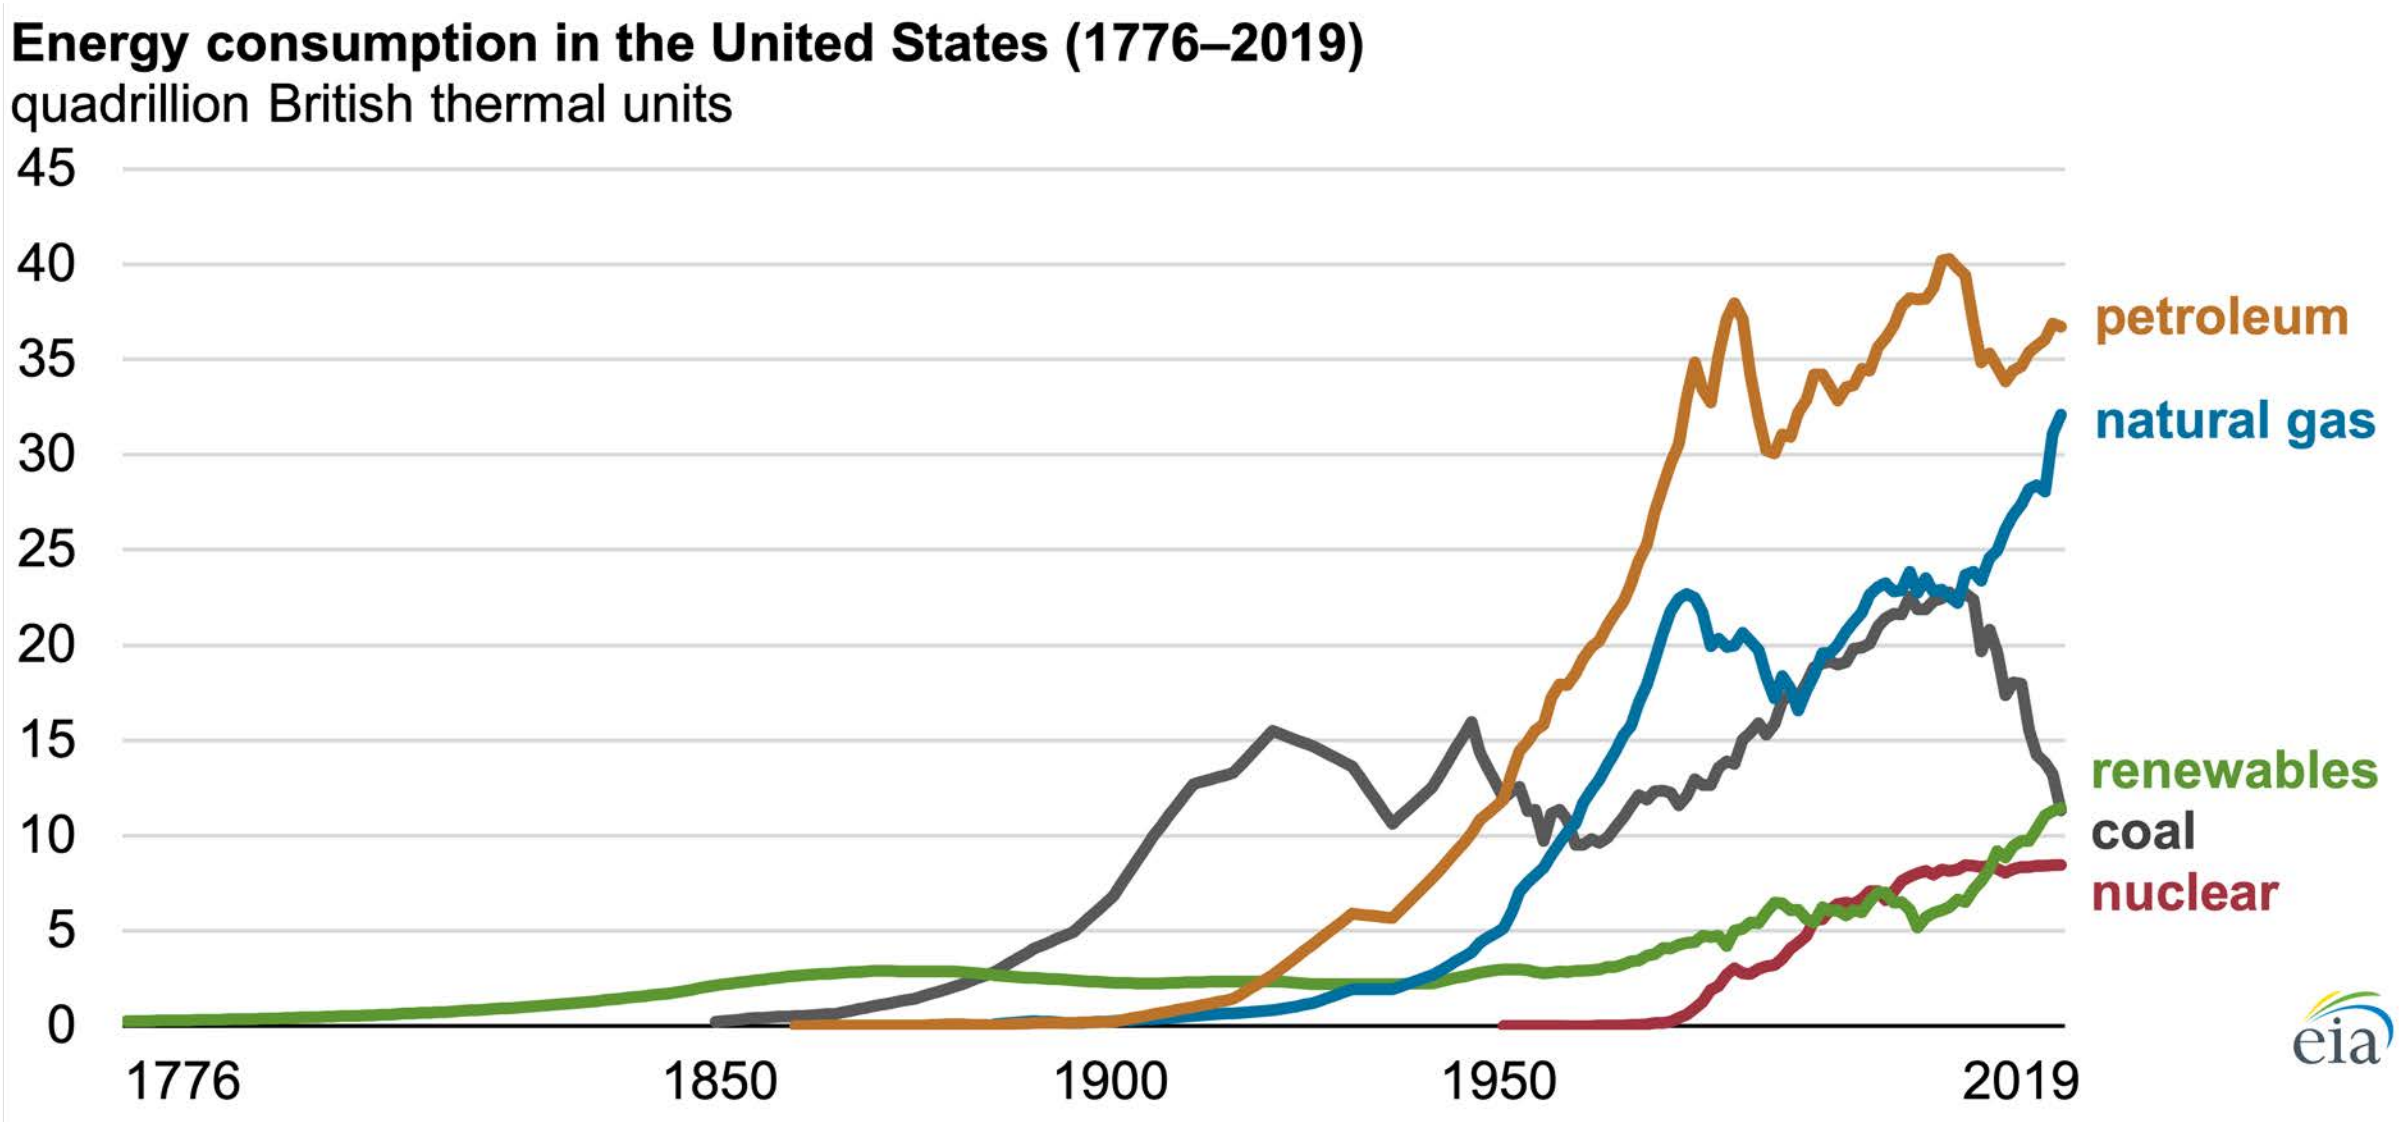
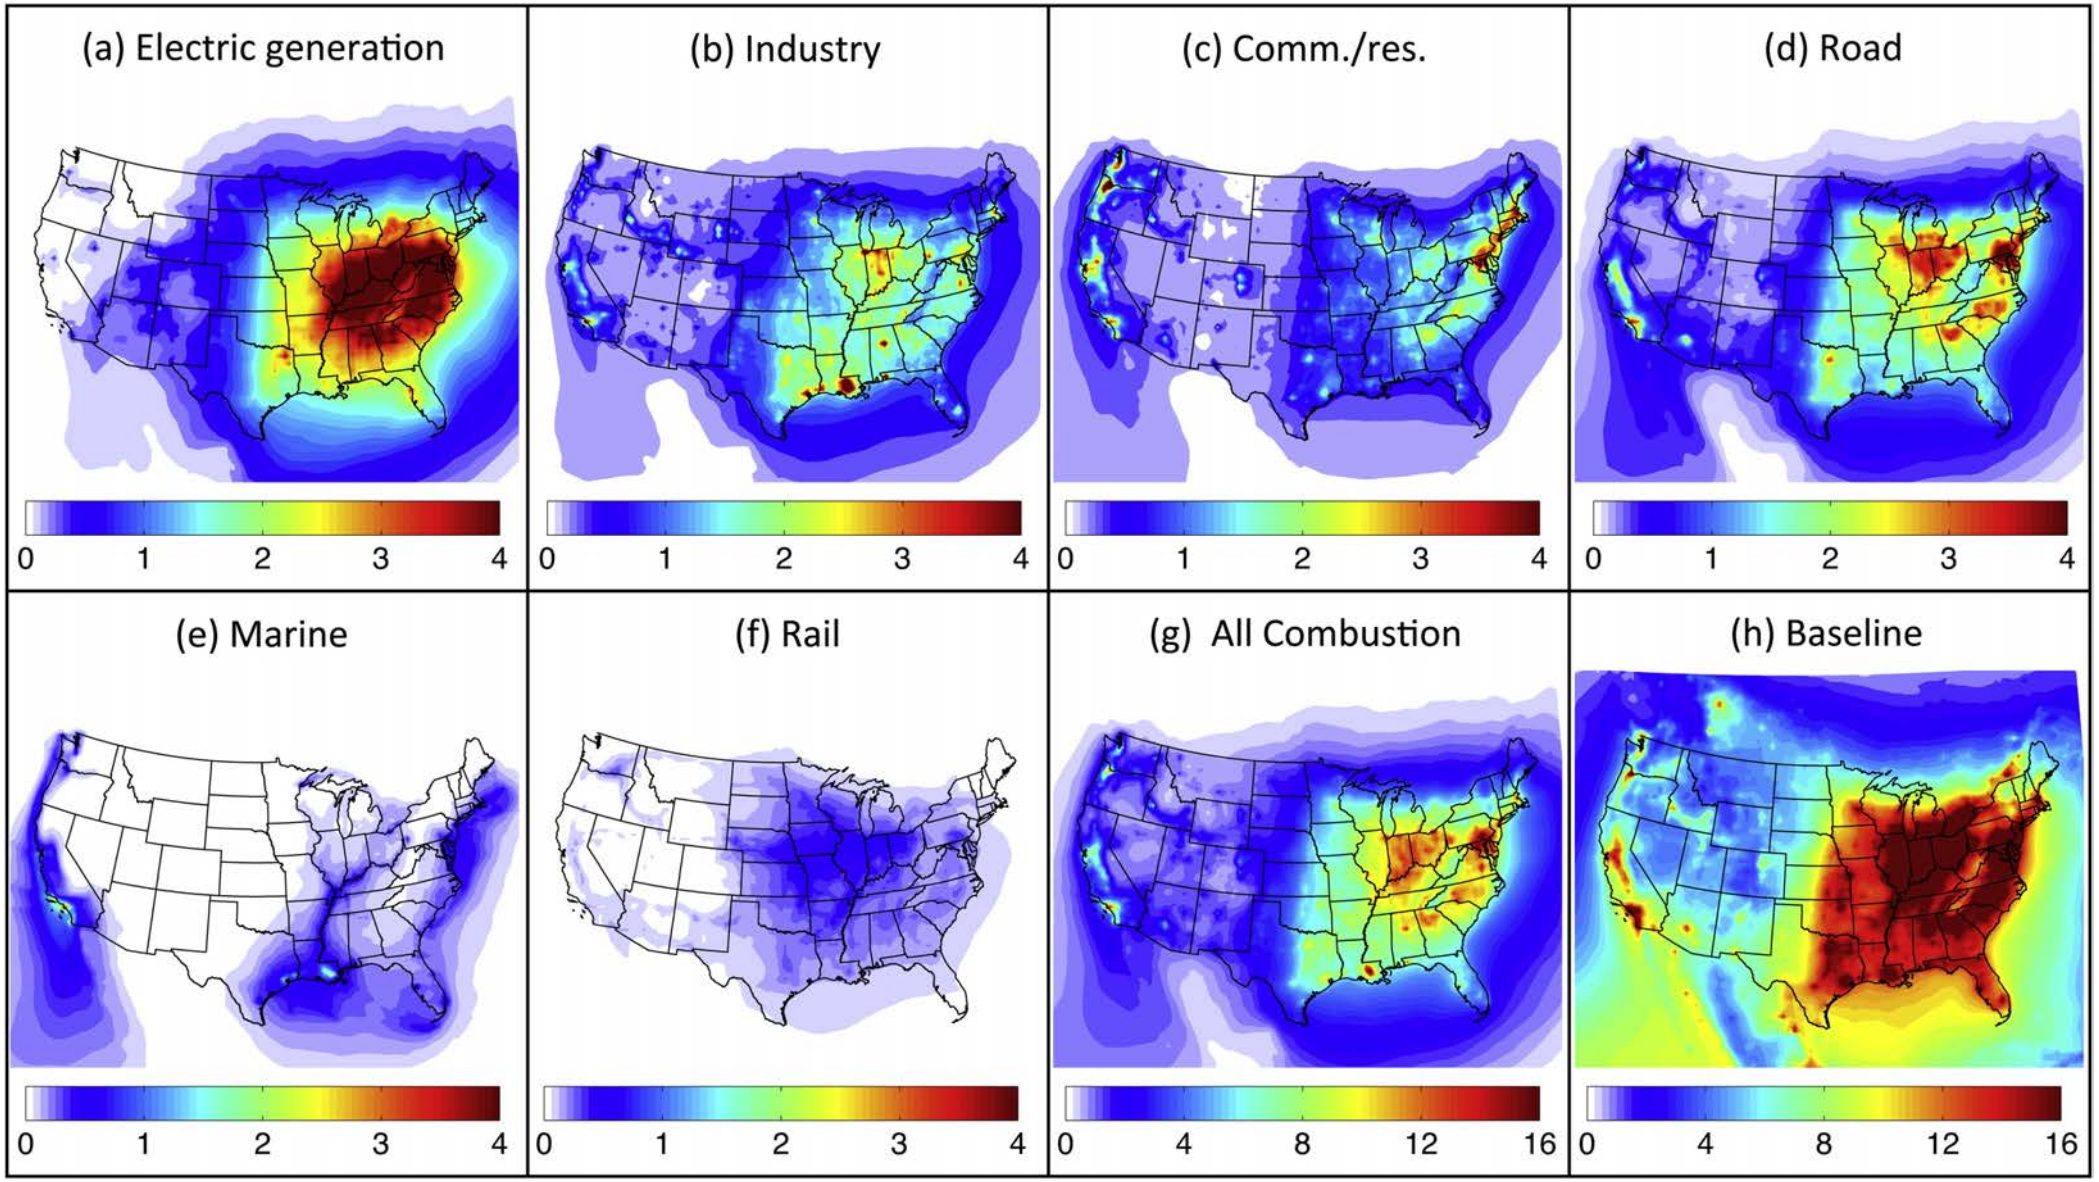
Reliance on oil and gas in the United States



[US EIA, 2020]

$PM_{2.5}$ concentration ($\mu g\ m^{-3}$) from combustion sources in the US

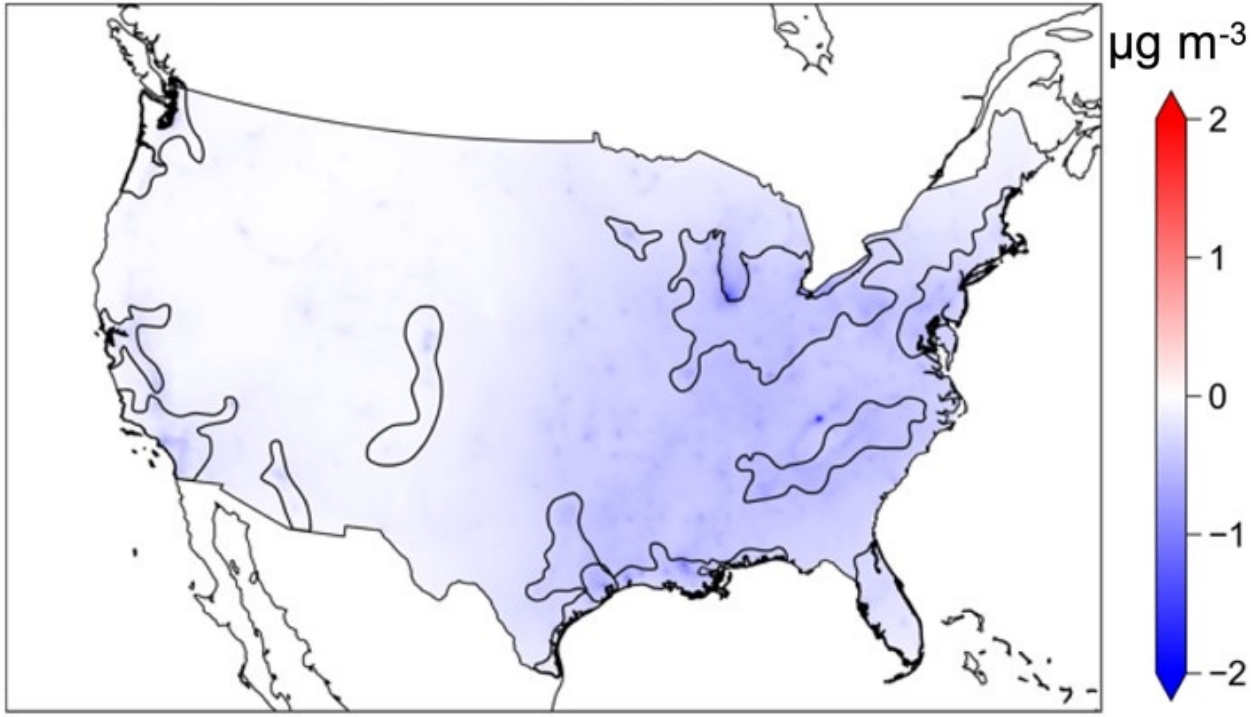


[Caiazzo et al, 2013]

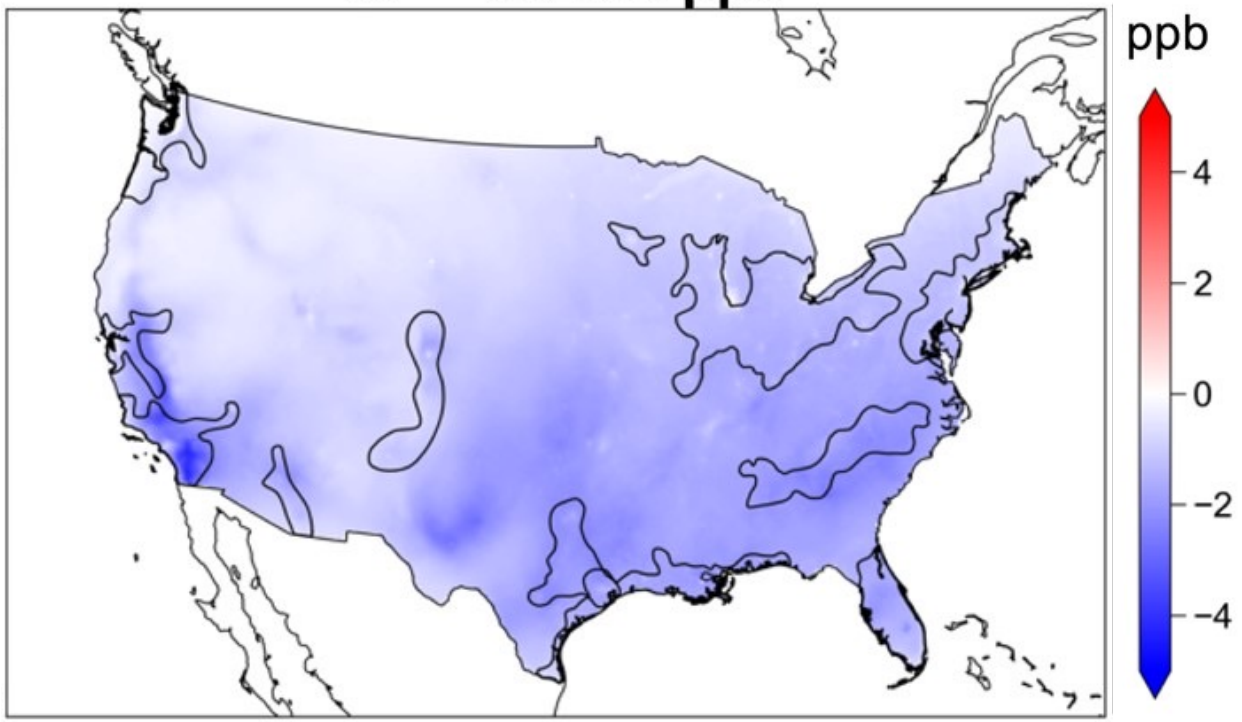
COVID-19 lockdowns provide an assessment of contribution of road traffic to air pollution

2020 minus 2019 (April-June)

$PM_{2.5}$ Δ = -0.4±0.2 µg m^{-3}



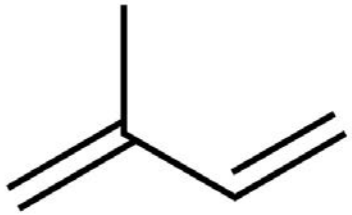
$MDA8O_3$ Δ = -1.4±0.6 ppb



… But occurrence of these lockdowns was limited to early spring. Summertime is onset of peak ozone pollution in eastern US and biogenic isoprene emissions in southeastern US

[He et al, 2024]

NO_x modulates the oxidative fate of isoprene



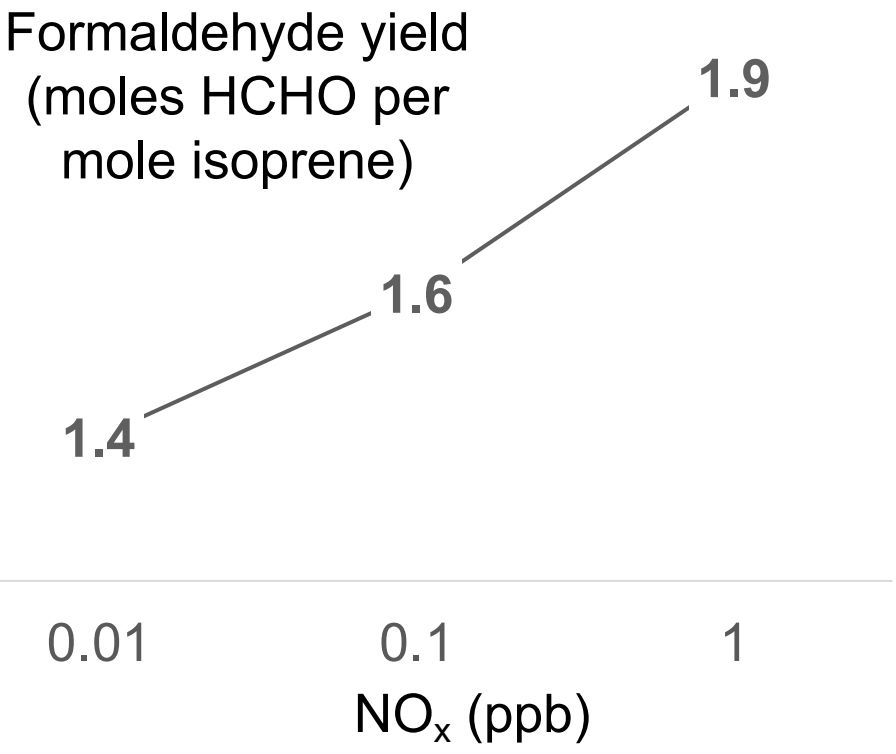
Isoprene

OH → Isoprene peroxy radical

NO 49%

HO_2 27%

Isoprene SOA precursors

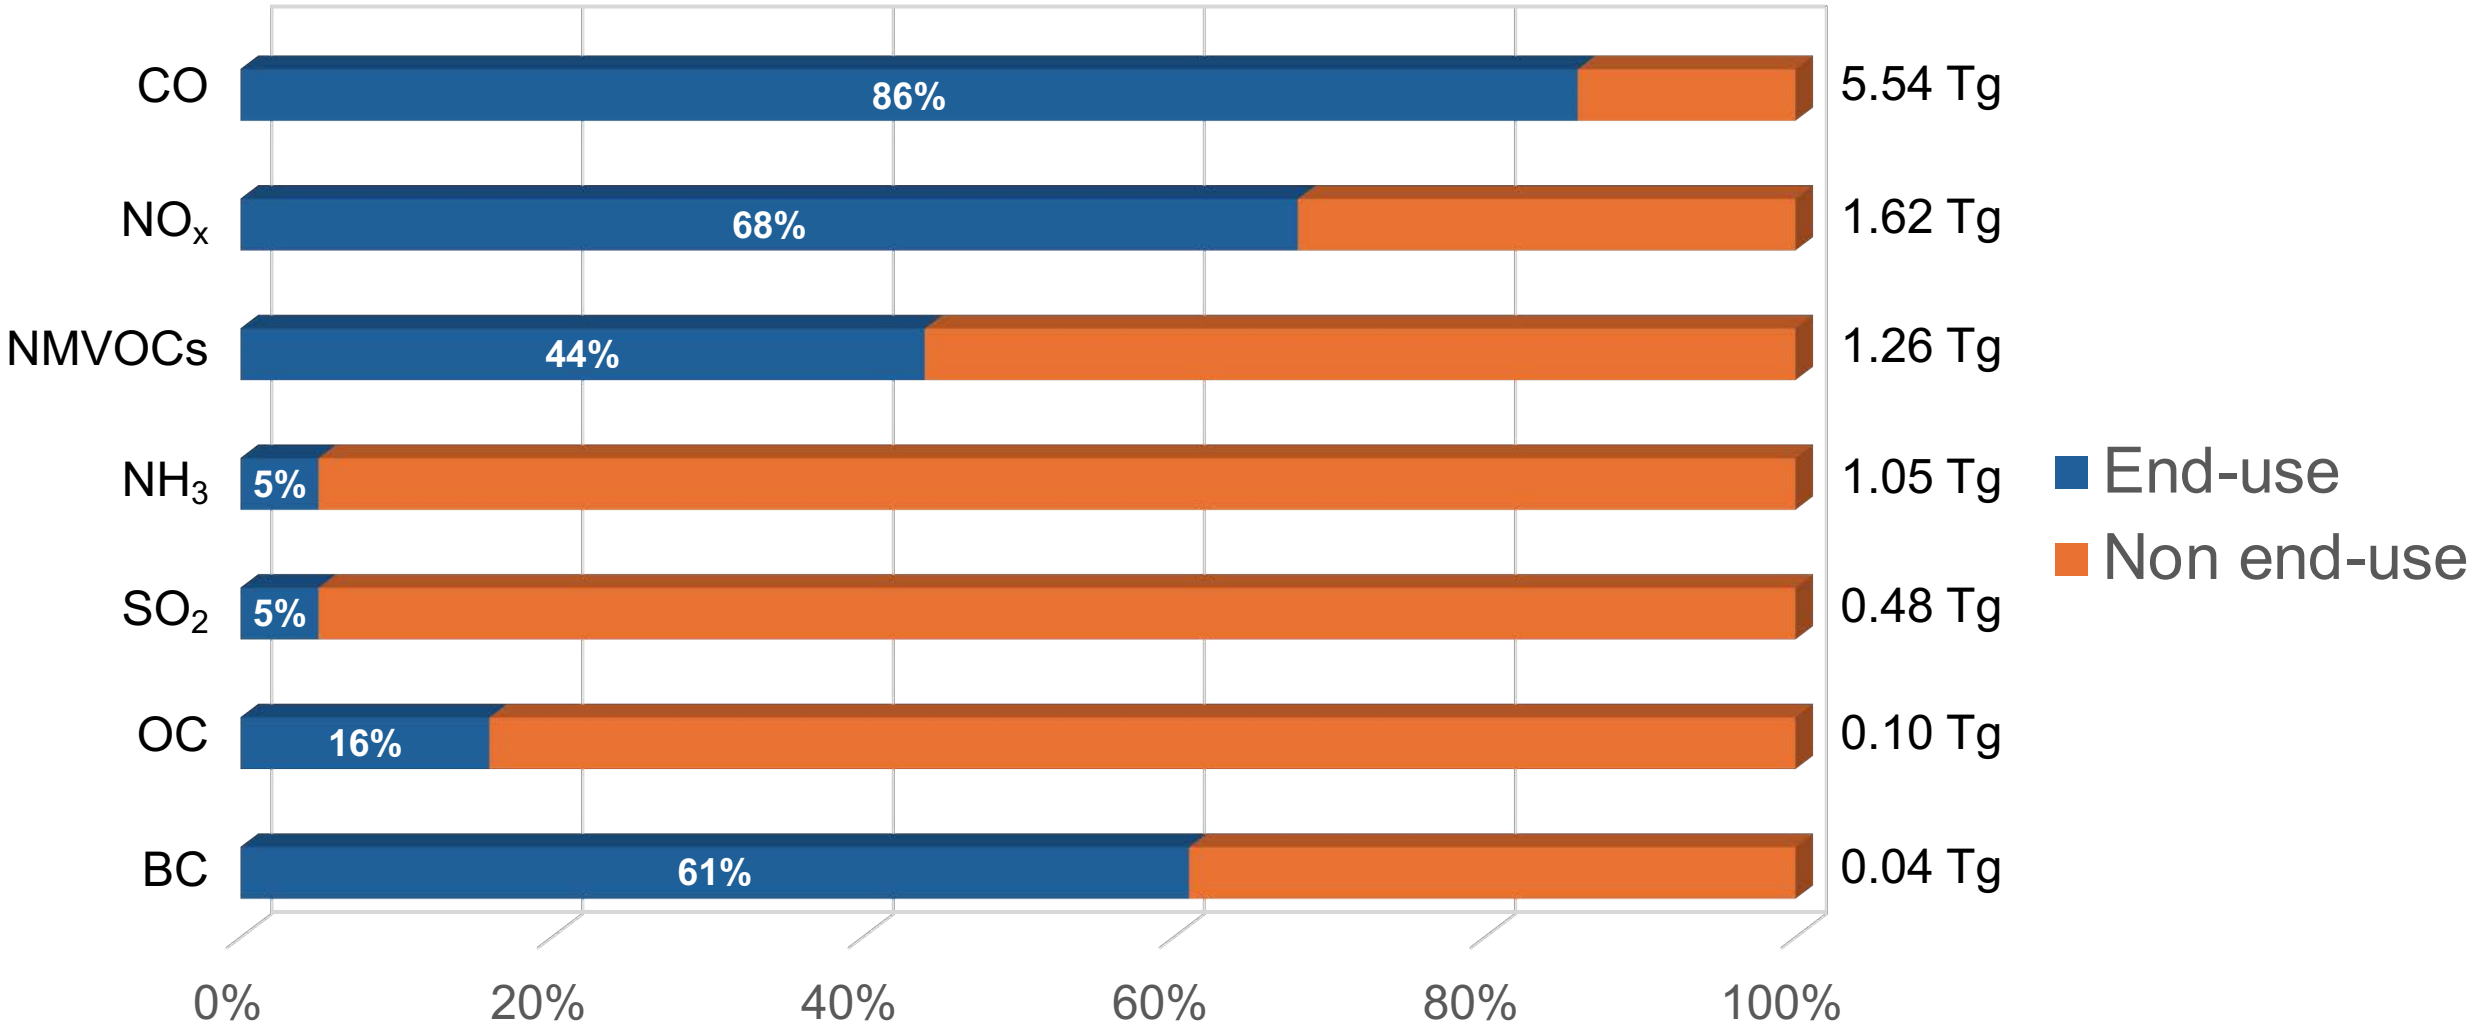


[Marais et al, 2012]

Here, we examine the influence of emissions from end-use activities on summertime ozone and $PM_{2.5}$ pollution

Contribution of end-use emissions to total anthropogenic emissions

We use FIVE for on-road and off-road mobile sources and NEI 2017 for all other anthropogenic sources



Dominant end-use activities: Mobile sources for CO and NO_x, diesel vehicles for BC and volatile chemical products for NMVOCs

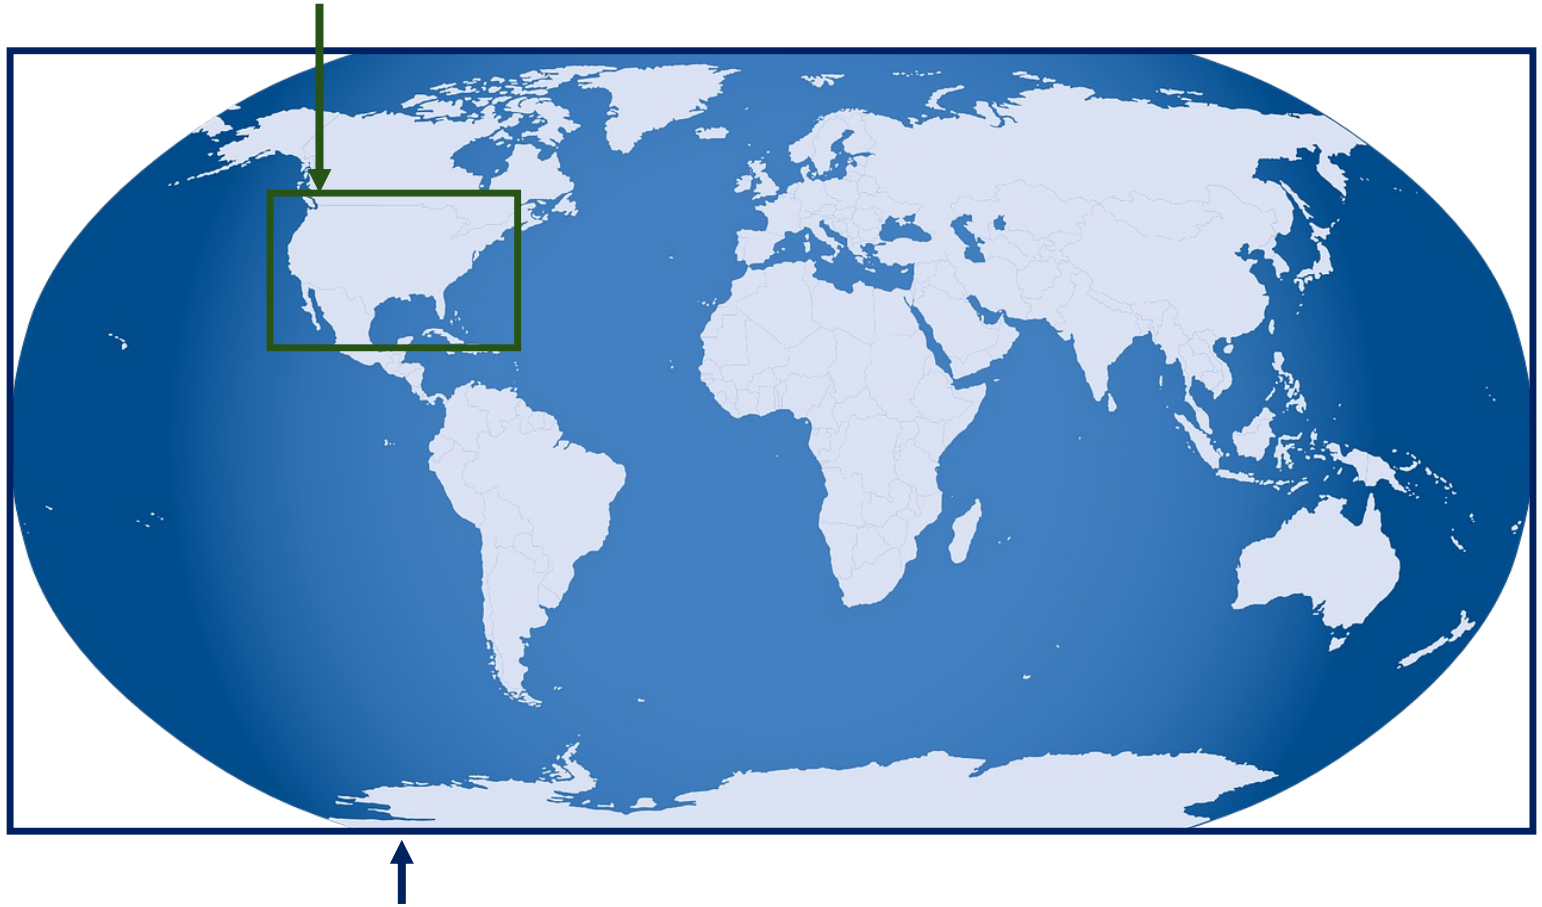
We use state-of-the-art 3D chemical transport model to simulate surface concentrations of atmospheric components

Emissions

GEOS Chem

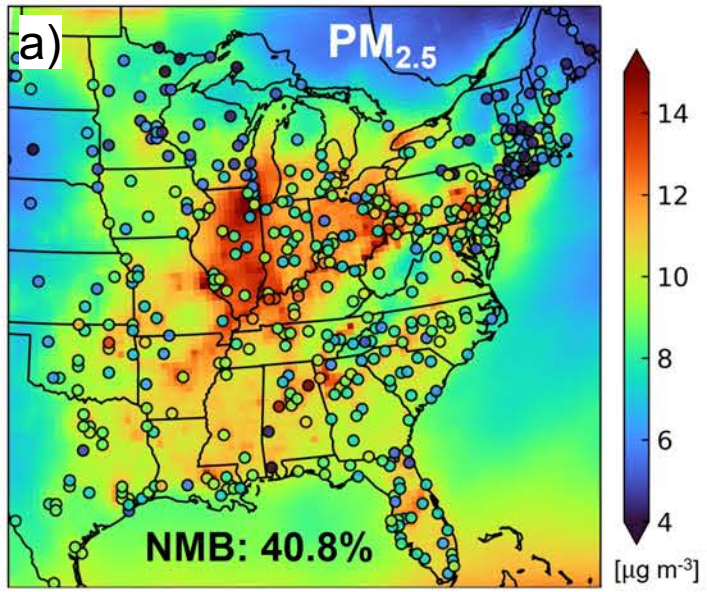
v13.0.0

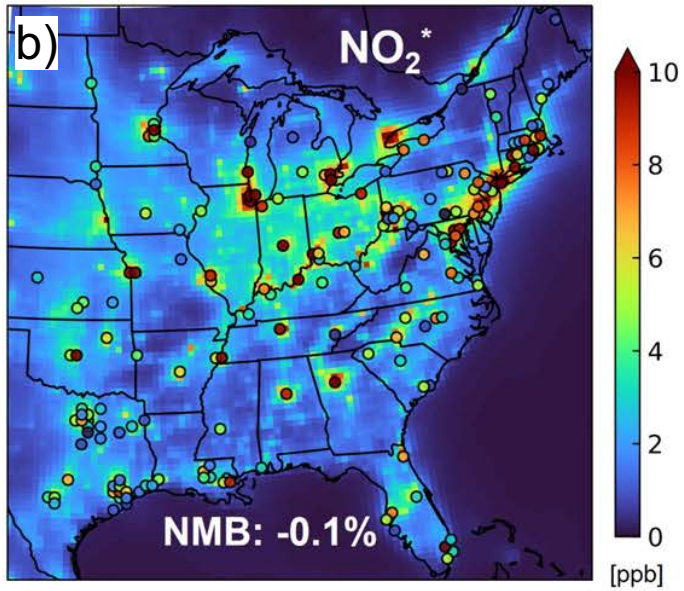
Meteorology

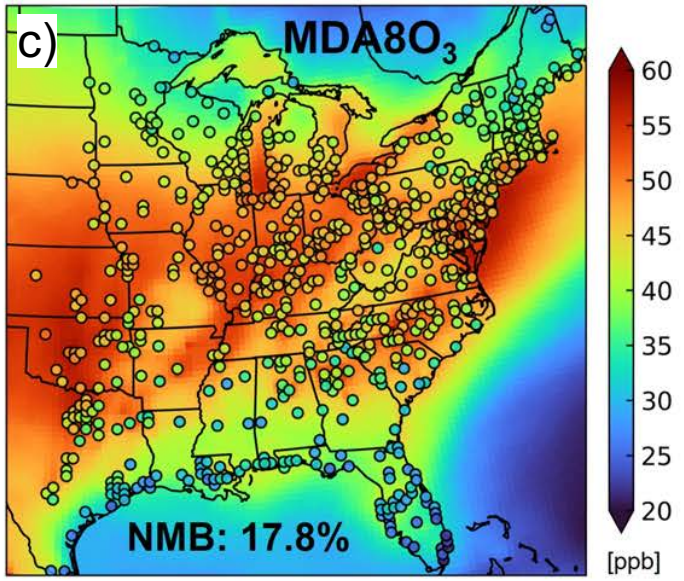


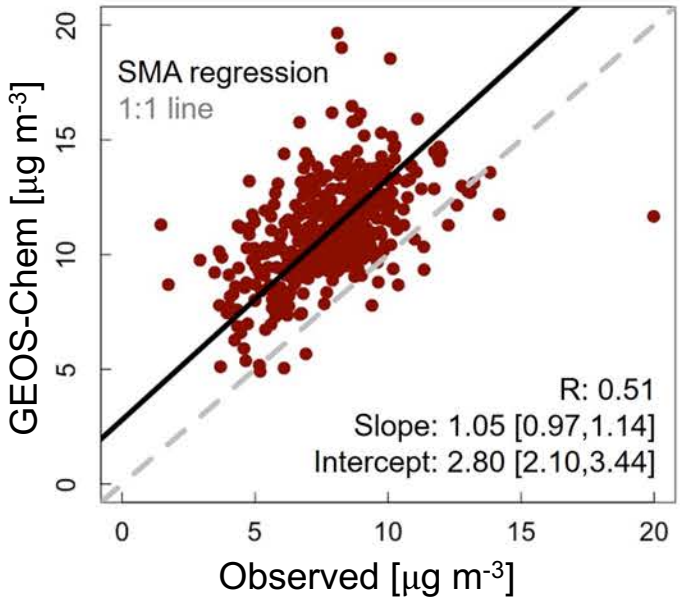
We run nested model with and without end-use emissions

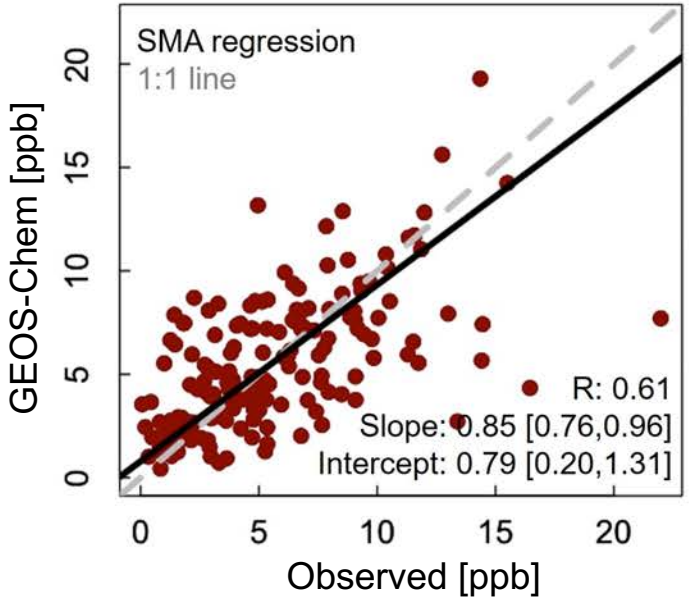
We evaluate model output against US EPA observations

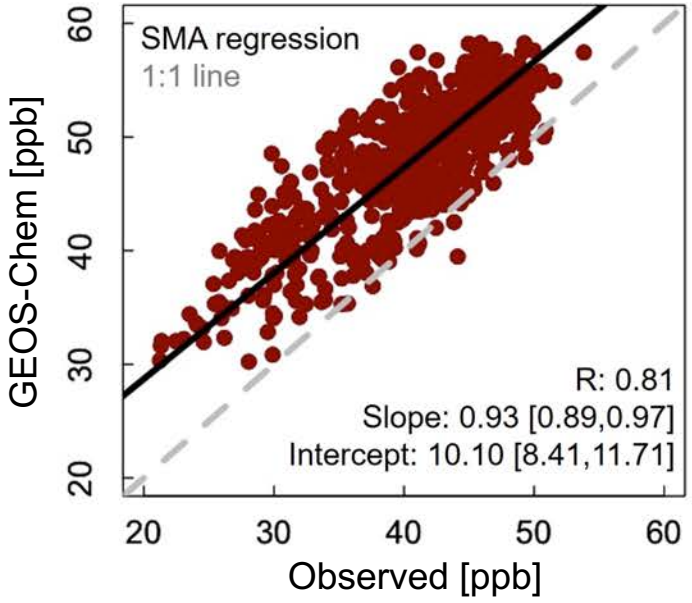






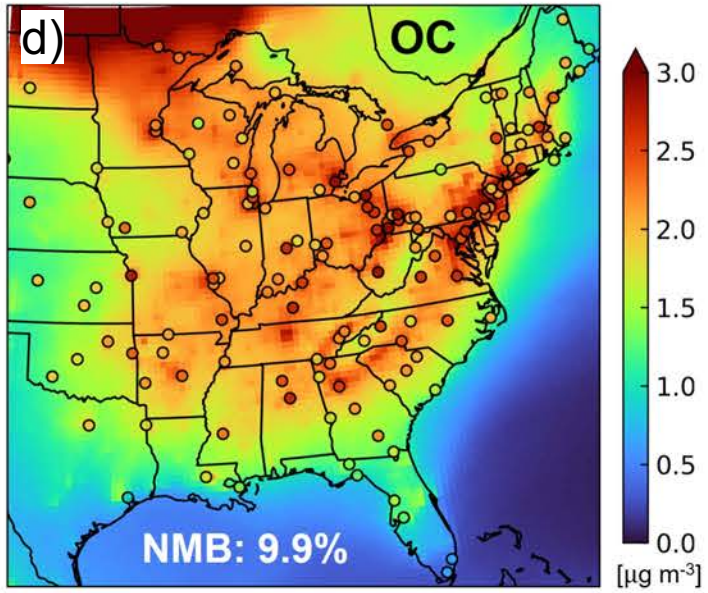


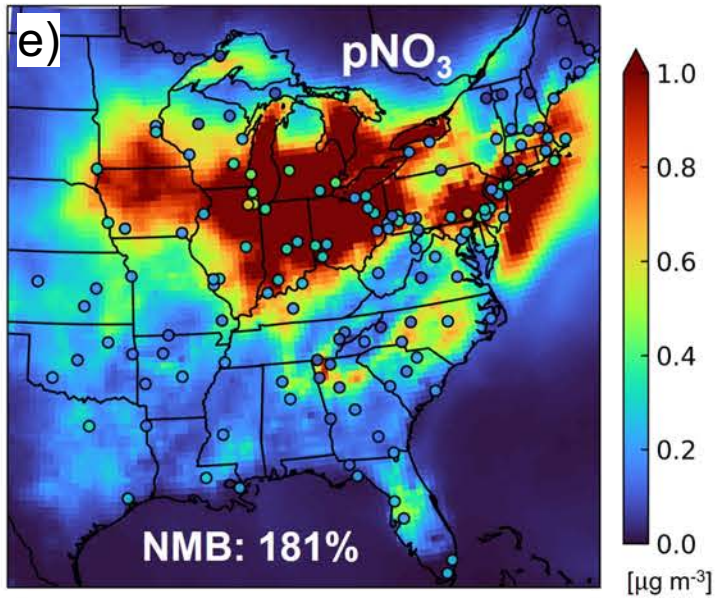


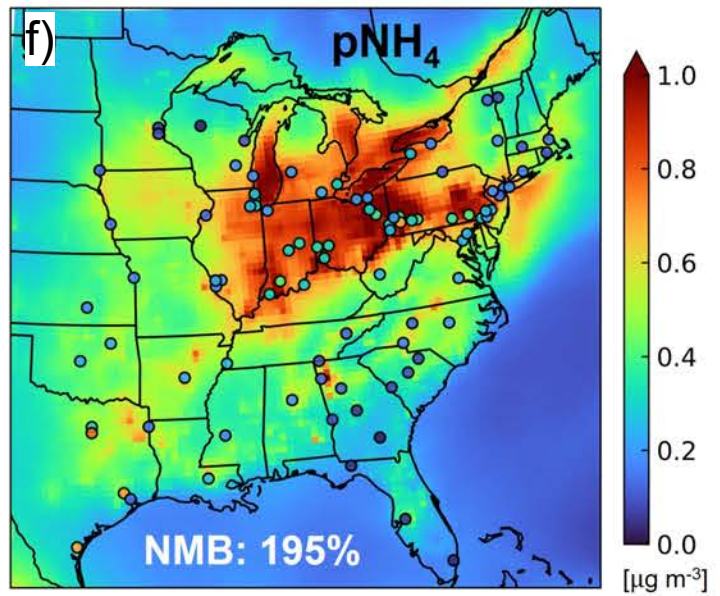


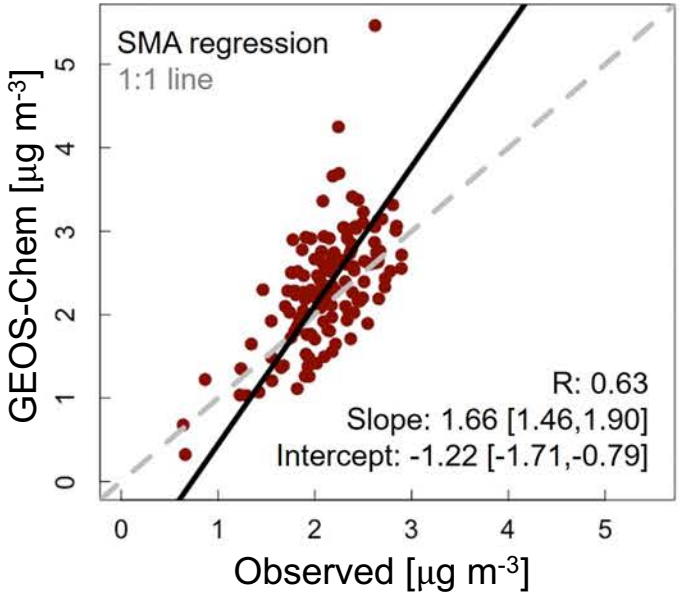
Regression slopes close to unity support use of GEOS-Chem for perturbation simulations

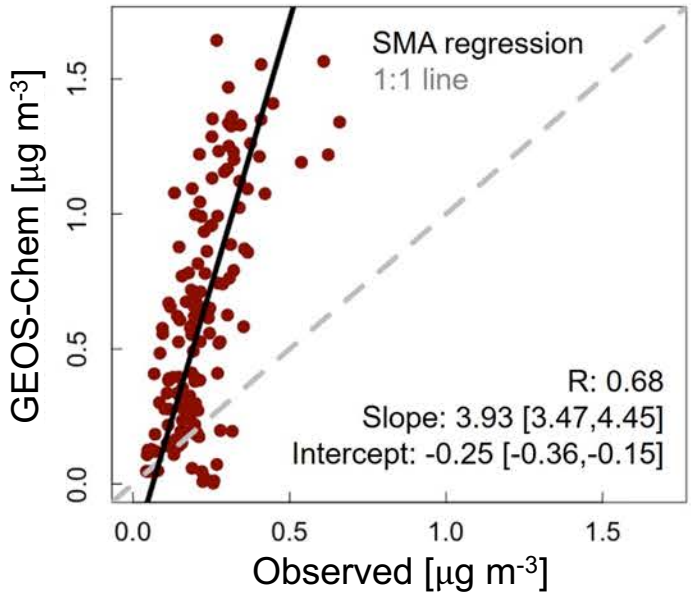
We evaluate model output against US EPA observations

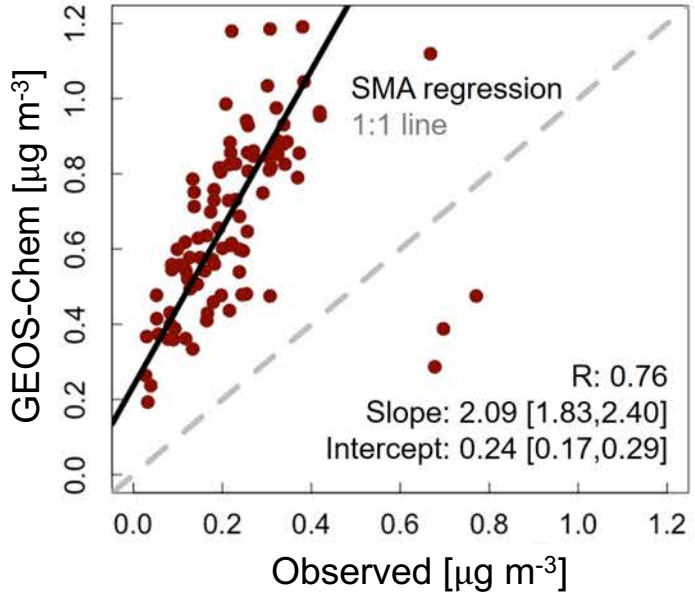










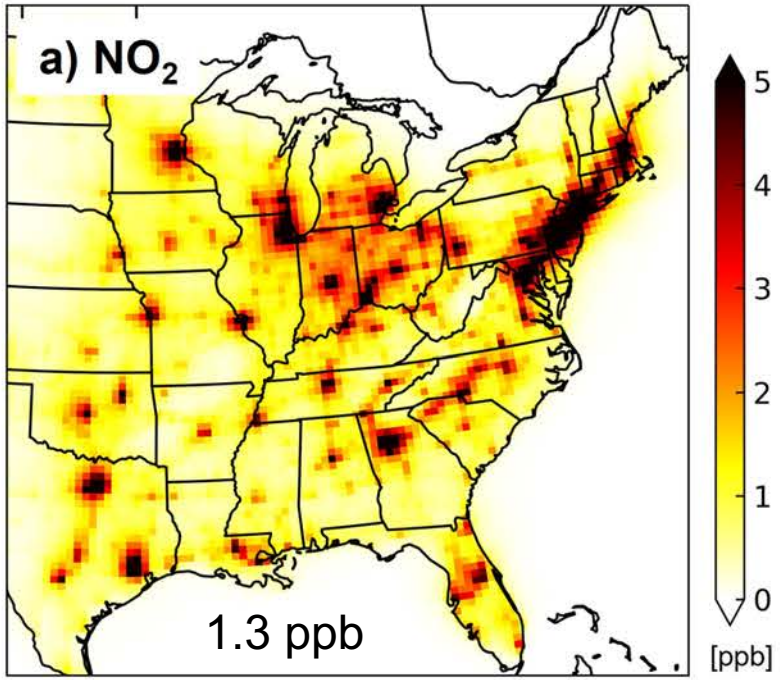


We correct for the 3-fold model overestimate in pNO_3 and pNH_4

Contribution of end-use activities to ozone and its precursors

Large contributions to summertime mean NO_x of up to 20 ppb;

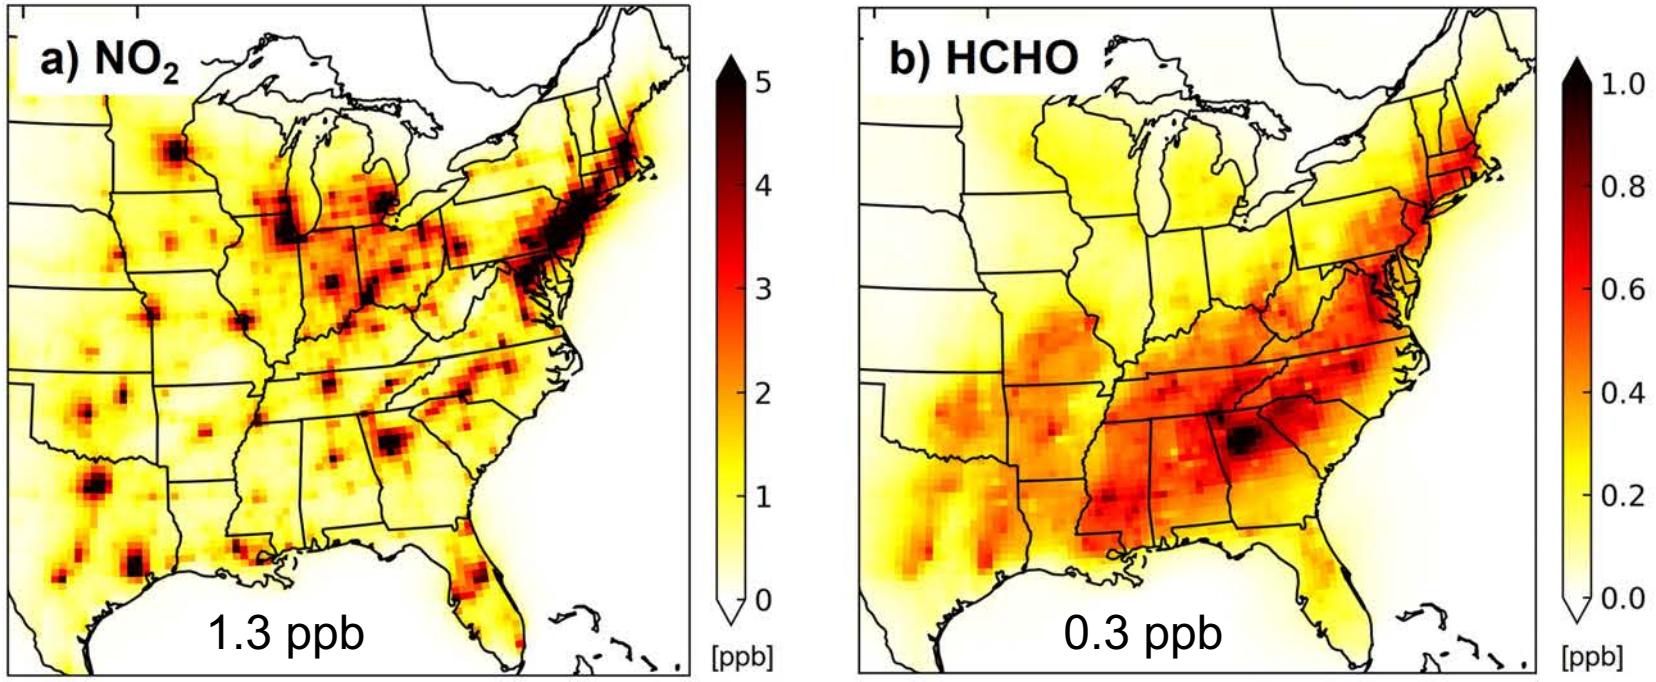
$NO\text{-to-}NO_2$ is small (9%) but end-use NO increases the proportion of isoprene oxidized by NO rather than by HO_2 from 42:30 to 49:27



Contribution of end-use activities to ozone and its precursors

Large contributions to summertime mean NO_x of up to 20 ppb;

$NO\text{-to-}NO_2$ is small (9%) but end-use NO increases the proportion of isoprene oxidized by NO rather than by HO_2 from 42:30 to 49:27

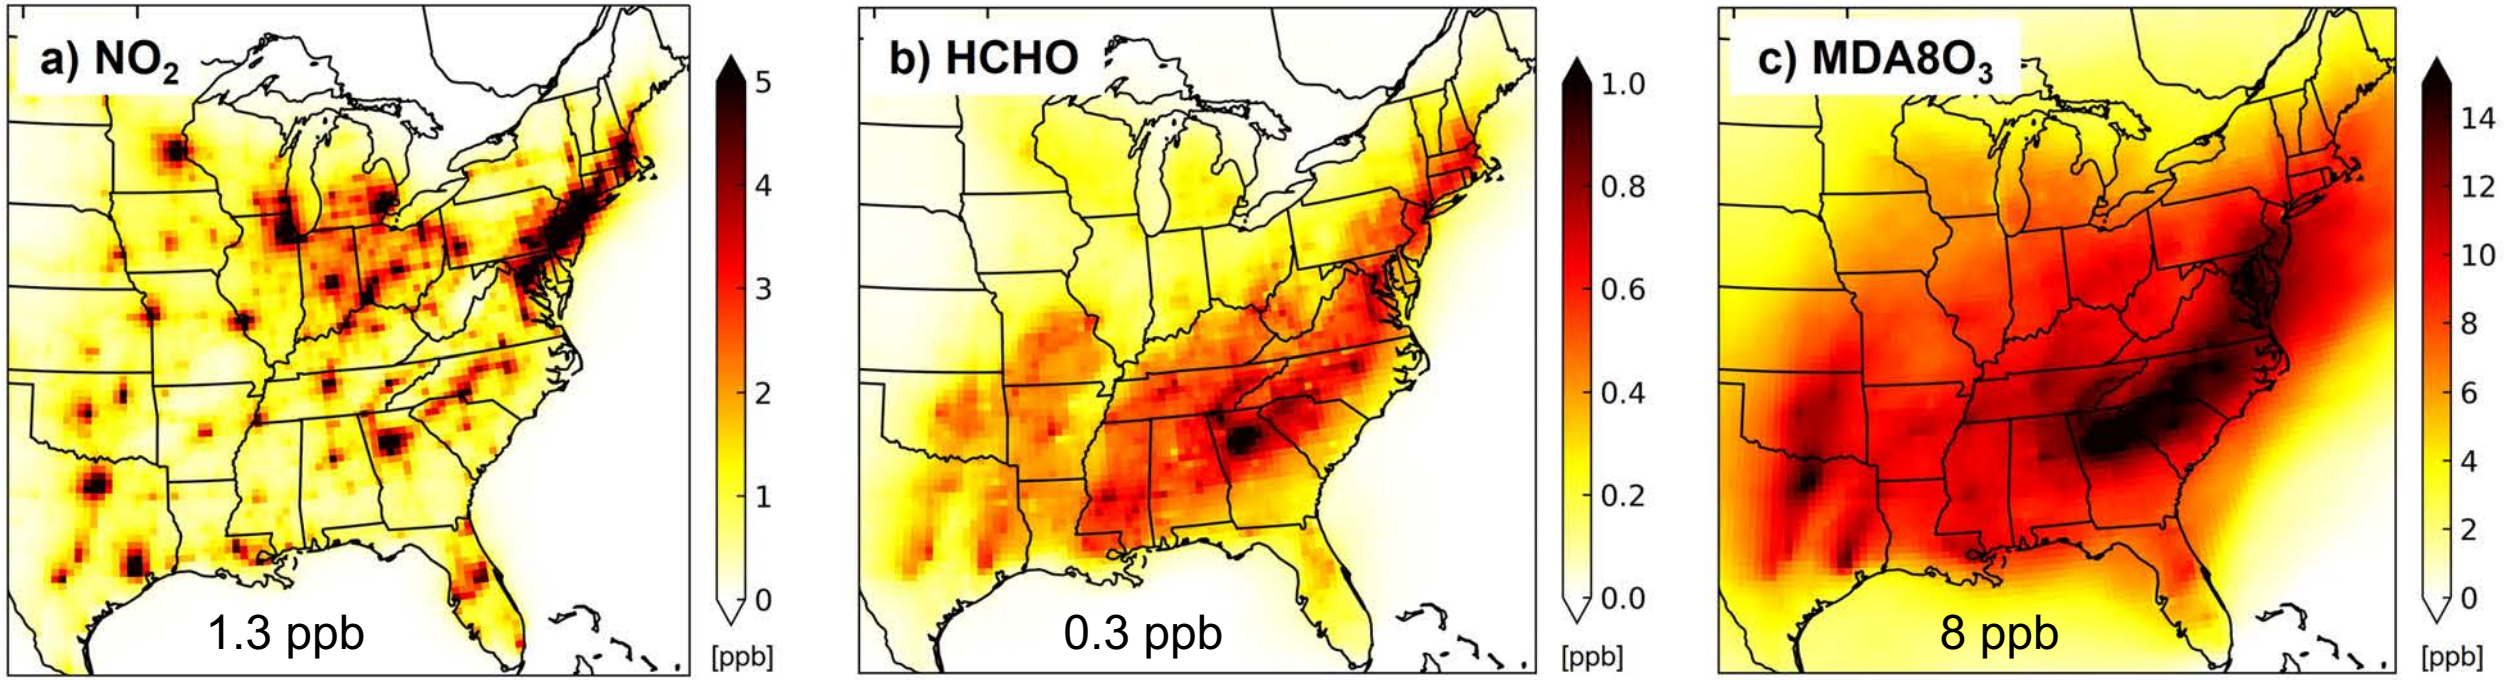


Large enhancements in formaldehyde (HCHO) from higher and more prompt HCHO yields via the NO isoprene oxidation pathway

Contribution of end-use activities to ozone and its precursors

Large contributions to summertime mean NO_x of up to 20 ppb;

$NO\text{-to-}NO_2$ is small (9%) but end-use NO increases the proportion of isoprene oxidized by NO rather than by HO_2 from 42:30 to 49:27

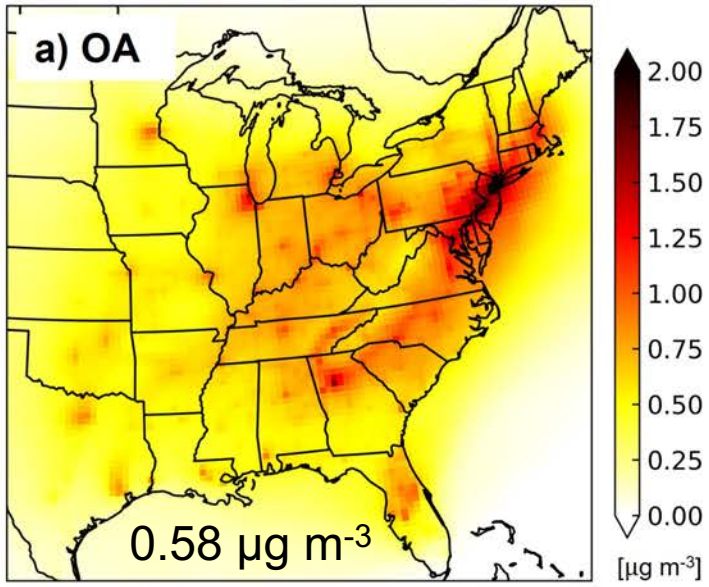


Large enhancements in formaldehyde (HCHO) from higher and more prompt HCHO yields via the NO isoprene oxidation pathway

Ozone production in this region is limited by availability of VOCs and the enhanced HCHO yields contribute to $MDA8O_3$

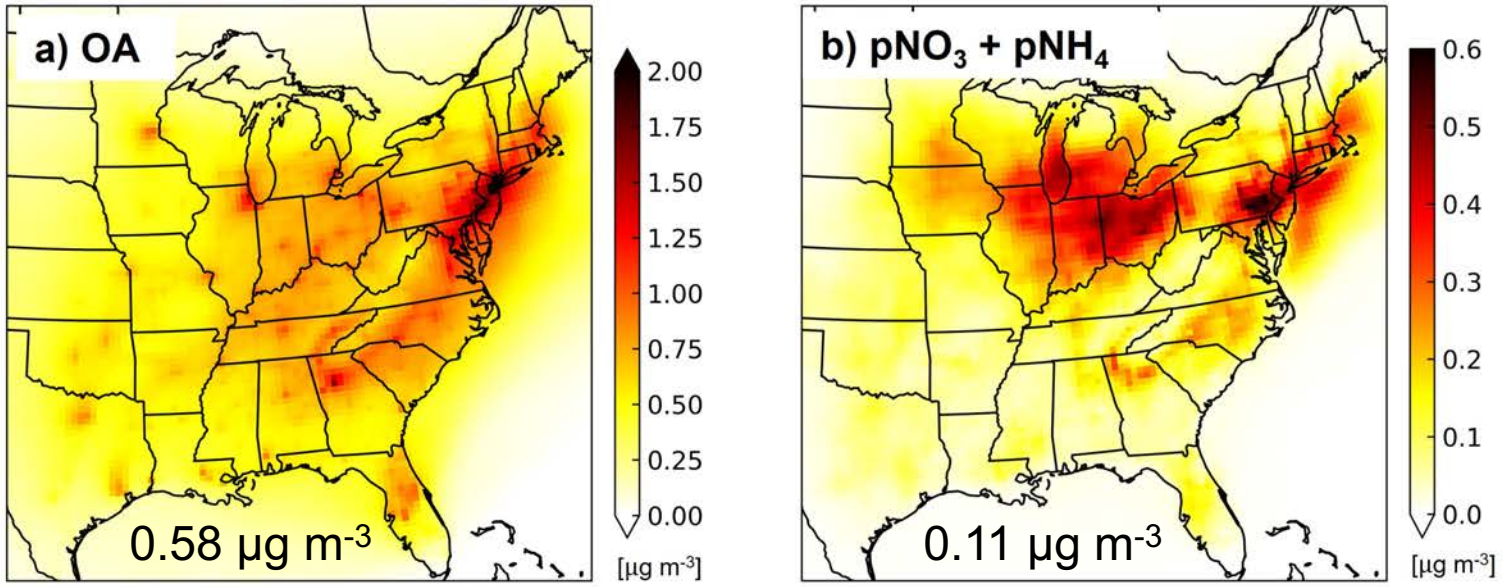
Contribution of end-use activities to $PM_{2.5}$ and its components

Most end-use $PM_{2.5}$ is anthropogenic OA



Contribution of end-use activities to $PM_{2.5}$ and its components

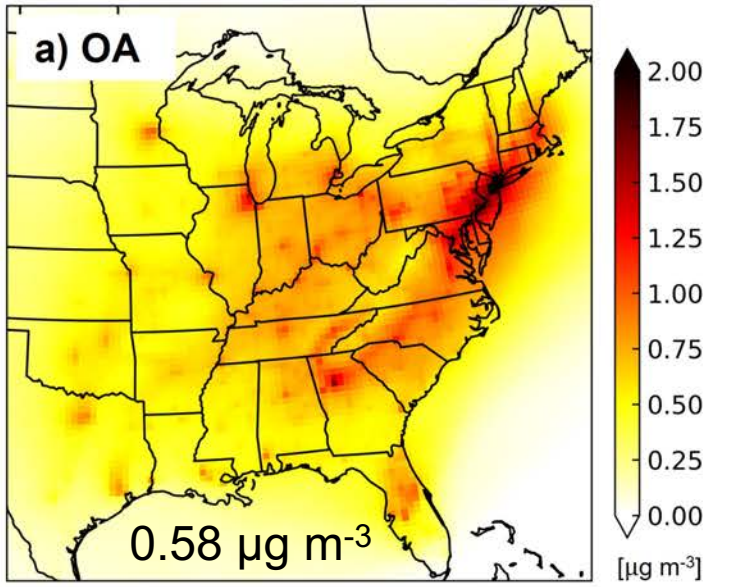
Most end-use $PM_{2.5}$ is anthropogenic OA

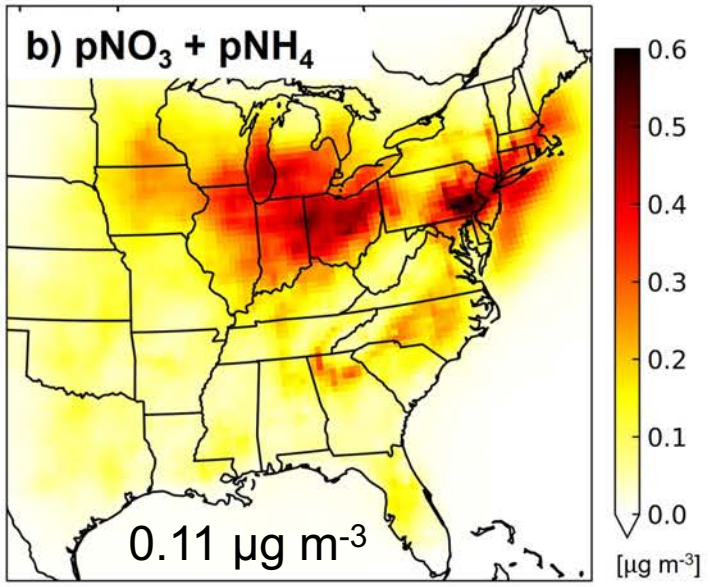


Acidic pNO_3 promotes uptake of ammonia

Contribution of end-use activities to $PM_{2.5}$ and its components

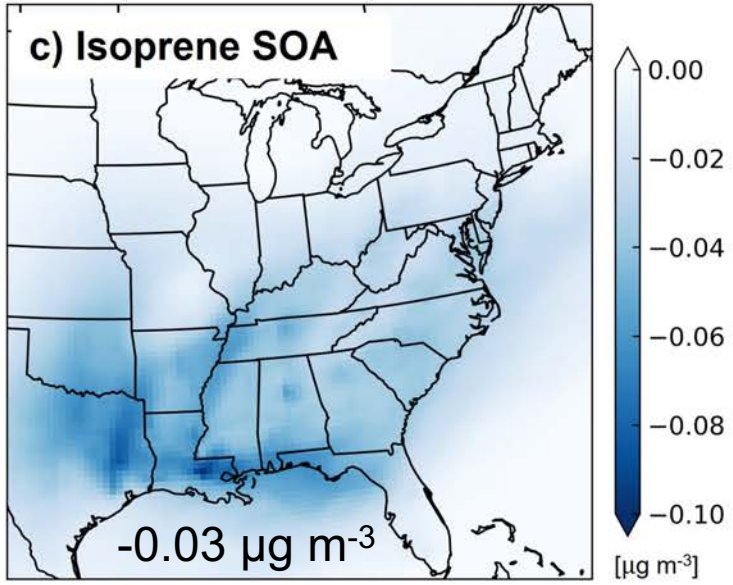
Most end-use $PM_{2.5}$ is anthropogenic OA





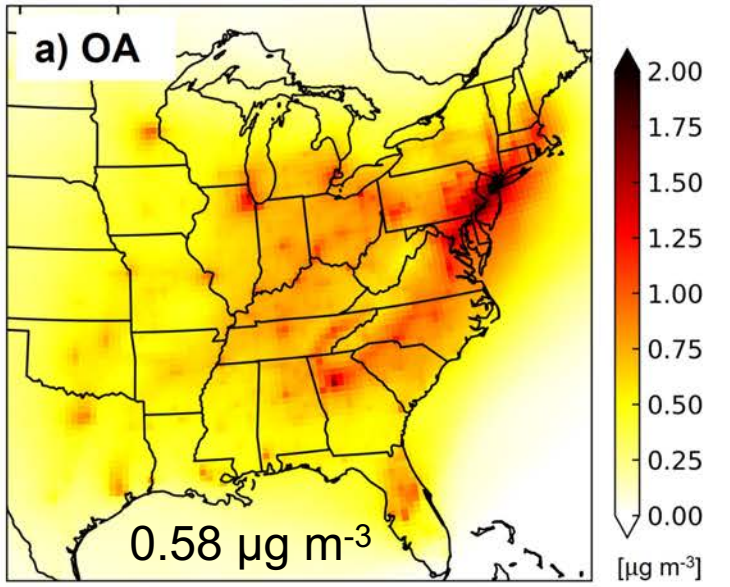
Acidic pNO_3 promotes uptake of ammonia

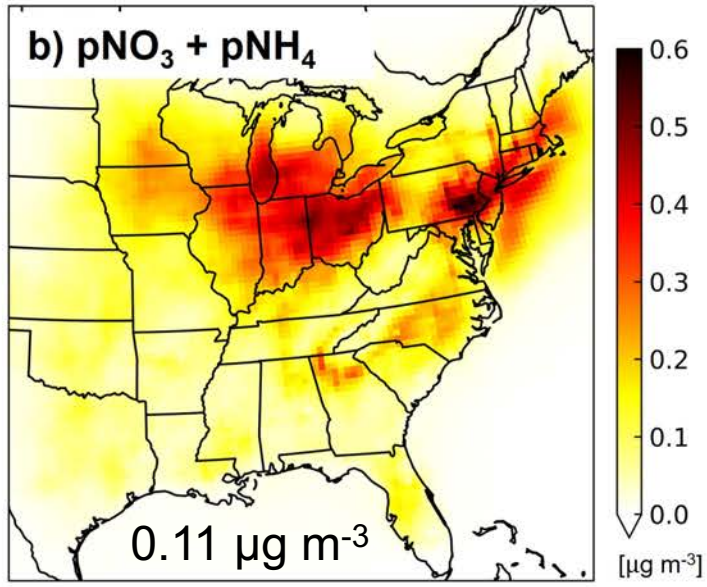
Reduction in HO_2 isoprene oxidation pathway



Contribution of end-use activities to $PM_{2.5}$ and its components

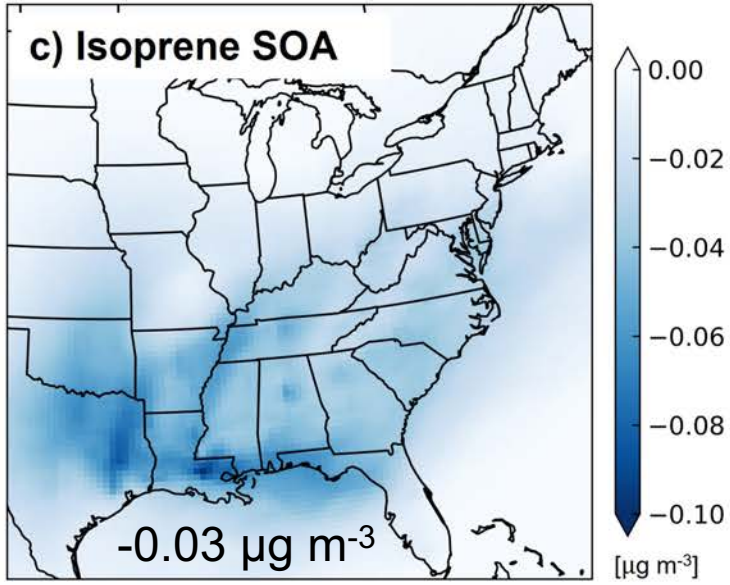
Most end-use $PM_{2.5}$ is anthropogenic OA

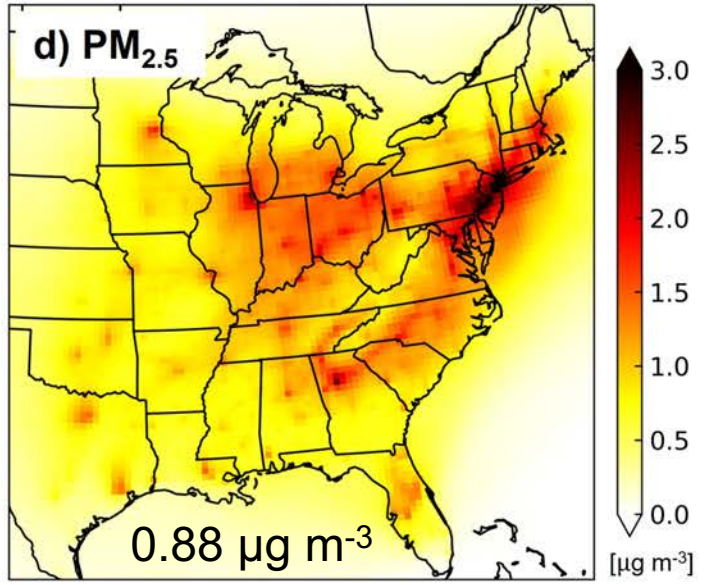




Acidic pNO_3 promotes uptake of ammonia

Reduction in HO_2 isoprene oxidation pathway





Net effect exceeds 3 µg m^{-3} mainly in cities and northeast coast

Influence of oil and gas end-use on eastern US summertime atmospheric composition
